# Lecture 8 Reactions of Ferrocene

# **Reactions of Metal Carbonyls**

### **Nucleophilic addition to CO**

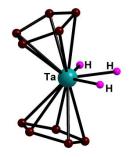

# **Migratory insertion of CO**

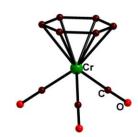

### **Fischer Carbene**

Carbenes are catalysts for olefin metathesis

# **Metal-Sandwich compounds**

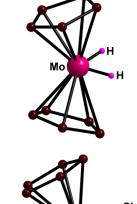

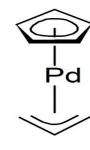

Hapticity of sandwich compounds varies from 1-8

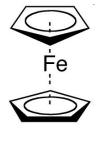

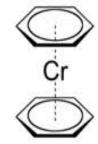

A transition-metal complex in which a metal atom or ion is 'sandwiched' between two rings of atoms.

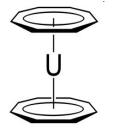

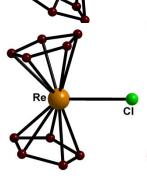

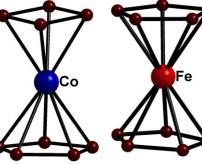

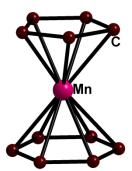

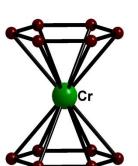

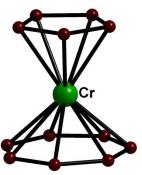

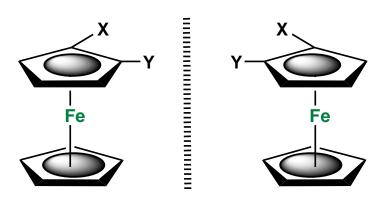

# Why metal – sandwich compounds are important?

- 1. Transition metal/ metal ion embedded inside an organic matrix: Makes a metal ion soluble even in hydrocarbon solvents. E.g. Ferrocene is soluble in hexane while Fe<sup>2+</sup> as such is not. Outcome: a hydrocarbon soluble additive/catalyst
- 2. Coordination to an electropositive metal often changes the reactivity and electronic properties of the  $\pi$  system bound to it (benzene vs ferrocene)
- 3. Metal sandwich compounds are excellent substrates to make planar chiral compounds. Applications as chiral catalysts in asymmetric catalysis

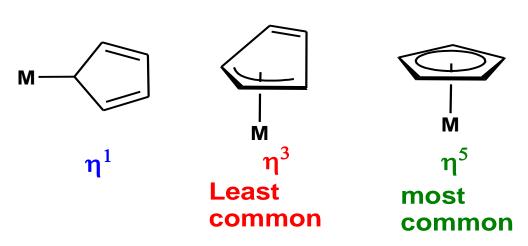

Planr chirality:

Non- super-imposable mirror images

# Cyclopentadienyl (Cp-)

•Cyclopentadienyl (Cp–) the most important of all the polyenyl ligands

Complex	Electron Count	$\Delta H$ for M <sup>2+</sup> -C <sub>5</sub> H <sub>5</sub> <sup>-</sup> Dissociation (kJ/mol)
$(\eta^5 - C_5 H_5)_2 Fe$	18	1470
$(\eta^5 - C_5 H_5)_2 Co$	19	1400
$(\eta^5$ -C <sub>5</sub> H <sub>5</sub> ) <sub>2</sub> Ni	20	1320

$$(\eta^5$$
-Cp) $(\eta^3$ -Cp)W(CO)<sub>2</sub>

Ferrocene shows much more chemical stability than cobaltocene and nickelocene; many of the chemical reactions of the latter are characterized by a tendency to yield 18-electron products.

# Synthesis of ferrocene and other metallocenes

- •Neutral cyclopentadiene (C<sub>5</sub>H<sub>6</sub>) is a weak acid with a pKa of around 15
- •Deprotonated with strong base or alkali metals to generate the anionic Cp-

$$MCI_2 + 2 Na[Cp] \longrightarrow (\eta^5-Cp)_2M + 2 NaCI$$

$$M = Cr, Mn, Fe, Co, Ni and Zn$$

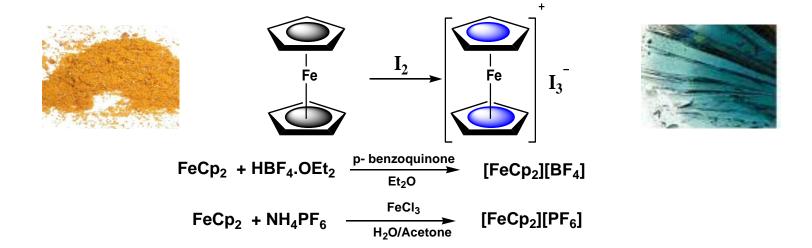

In a sandwich complex, the metal centre lies between two  $\pi$ -bonded hydrocarbon (or derivative) ligands. Complexes of the type  $(\eta^5\text{-Cp})_2\text{M}$  are called *metallocenes*.

$$MCI_2 + 2 C_5H_6 + 2 Et_2NH$$
  $\longrightarrow$   $(\eta^5-Cp)_2M + 2 [Et_2NH_2]CI$   $M = Fe, Ni$ 

### **Reactions of Ferrocene**

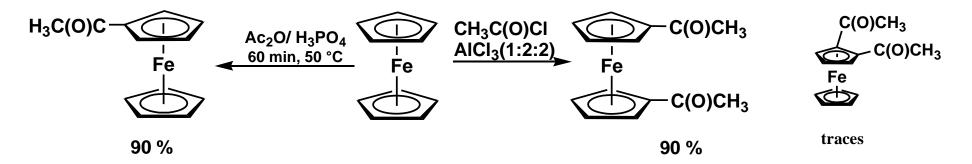

Ferrocene undergoes electrophilic substitution reactions. Many of its reactions are faster than similar reactions of benzene

Necessary requirement: The electrophile should not be oxidizing in nature

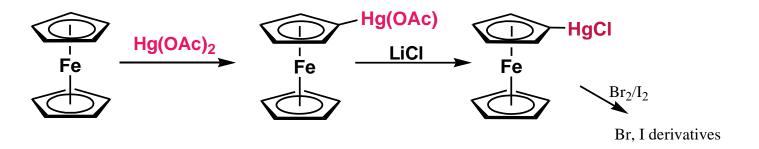

The oxidized Cp<sub>2</sub>Fe<sup>+</sup>, ferrocenium cation, will repel the electrophile away. Therefore direct nitration, halogenation and similar reactions cannot be carried out on ferrocene.

### Acetylation

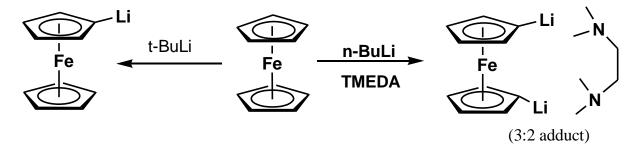

### **Chloromercuration** (hazardous)

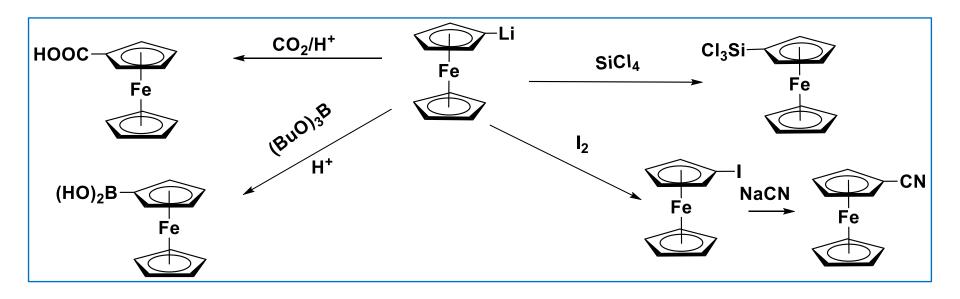

### 109 times faster than benzene

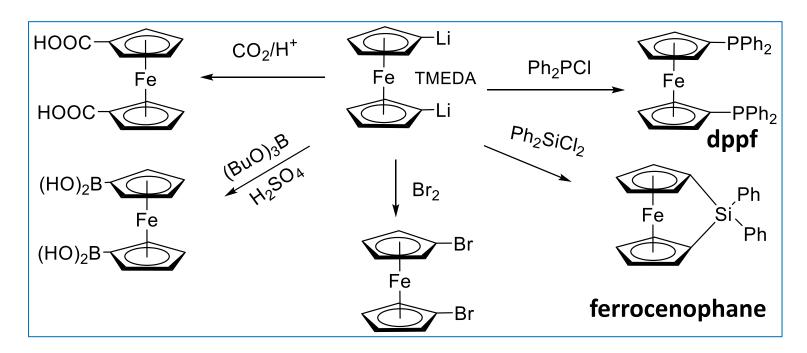

### **Lithiation reaction**

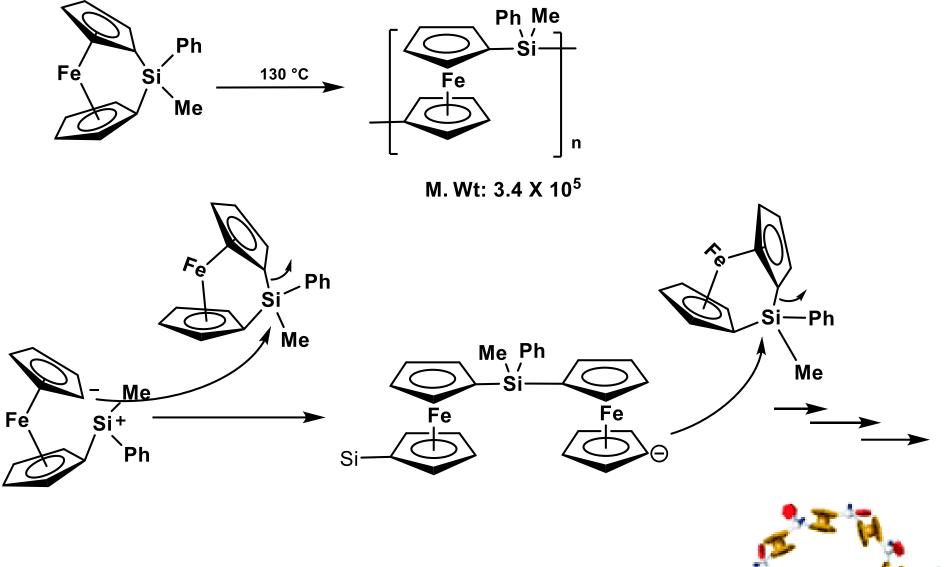

Does not happen with benzene; only with bromobenzene

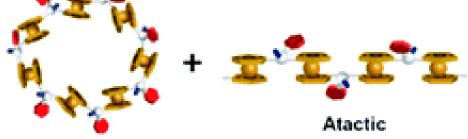

# Lithiation and 1,1'-di-lithiation – access to range of new derivatives

# Polymers with ferrocene in the backbone

## **Problem solving - synthesis**

Starting from ferrocene show minimum number of steps for preparing 1,1'- ferrocene dicarboxylic acid

# **Organometallic Reaction Mechanism**

**Common paths in organometallic reactions** 

- 1. Oxidative addition
- 2. Reductive elimination
- 3. Migratory Insertion
- 4. β-hydrogen elimination
- 5.  $\sigma$ -bond metathesis

### **Oxidative addition**

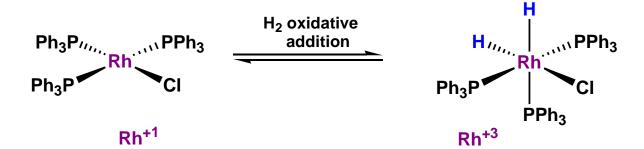

When addition of ligands is accompanied by oxidation of the metal, it is called an oxidative addition reaction

$$L_nM^n + XY \longrightarrow L_n(X)(Y)M^{n+2}$$

OX state of metal increases by 2 units

Coordination number increases by 2 units

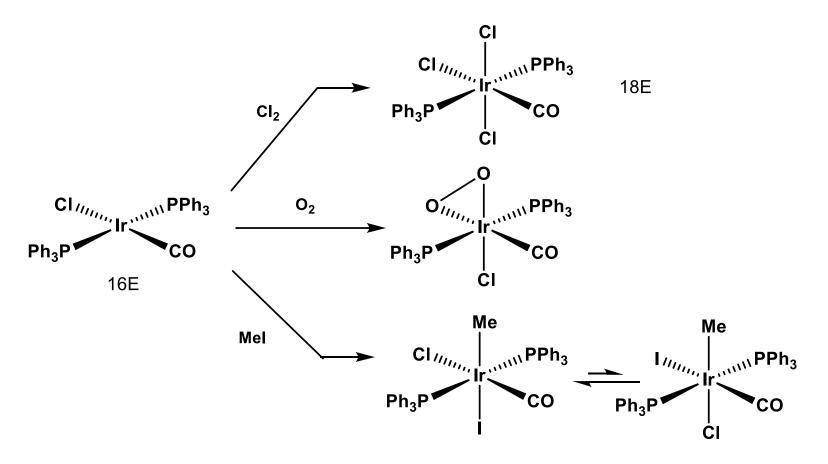

2 new anionic ligands are added to the metal

### Requirements for oxidative addition

- Availability of nonbonded electron density on the metal
- Two vacant coordination sites on the reacting complex (L<sub>n</sub>M), that is, the complex must be coordinatively unsaturated
- A metal with stable oxidation states separated by two units; the higher oxidation state must be energetically accessible and stable.

# **Examples of Oxidative addition : Cis or trans?**

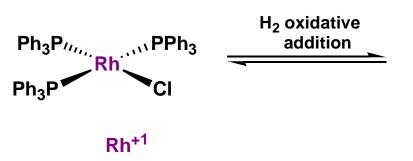

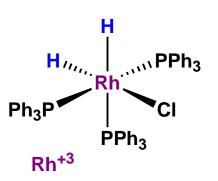

Homonuclear systems  $(H_2, Cl_2, O_2, C_2H_2)$  Cis

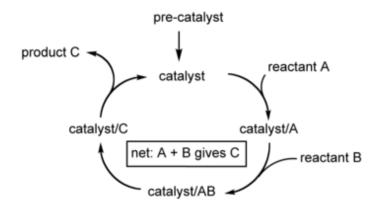

Heteronuclear systems (MeI) Cis or trans

# An important step in many homogeneous catalytic cycles

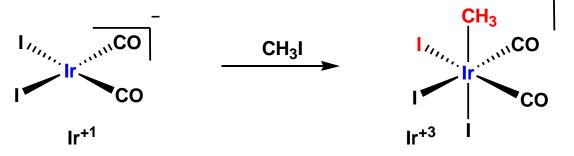

Hydrogenation of alkenes- Wilkinson catalyst

Methanol to acetic acid conversion- Cativa process

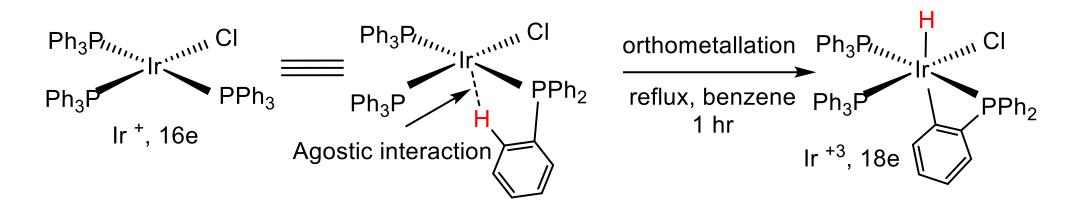

Often the first step of the mechanism

Pd catalyzed Cross coupling of  $Ar-B(OH)_2$  and Ar-X - Suzuki Coupling

$$\begin{bmatrix} Ph_3P - Pd - PPh_3 \end{bmatrix} \qquad \begin{array}{c} & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & &$$

The more electron rich the metal, more easy is the oxidative addition

# Oxidative addition involving C-H bonds and cyclo/ortho metallation

Orthometallations, oxidative additions in which an ortho position of an aromatic ring becomes attached to the metal, are quite common.

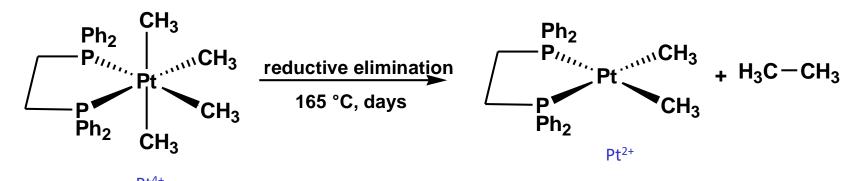

### Oxidative addition at a binuclear complex

$$(CO)_5Mn$$
 —  $Mn(CO)_5$  +  $Br_2$  —  $\longrightarrow$  2  $Mn(CO)_5Br$ 

For a binuclear complex oxidative addition increases oxidation state of metal by one each.

### **Reductive elimination**

#### Almost the exact reverse of Oxidative Addition

Oxidation state of metal decreases by 2 units

Coordination number decreases by 2 units

2 cis oriented anionic ligands form a stable  $\sigma$  bond and leave the metal

### Factors which facilitate reductive elimination

- A high formal positive charge on the metal,
- The presence of bulky groups on the metal, and
- An electronically stable organic product.

Cis orientation of the groups taking part in reductive elimination is a MUST

# Final step in many catalytic cycles

Hydroformylation (conversion of an alkene to an aldehyde)

Sonogashira Coupling (coupling of a terminal alkyne to an aryl group

$$R' \longrightarrow Pd \longrightarrow PR_3 \xrightarrow{\text{reductive elimination}} R' \longrightarrow Ar + \begin{bmatrix} R_3P - Pd - PR_3 \end{bmatrix}$$

$$PR_3$$

Mechanism of trans to cis conversion

$$H_3C_{N_1}$$
  $Pd$ 
 $CH_3$ 
 $CH_3$ 
 $S = Solvent$ 
 $S = Solvent$ 

# **Migratory Insertion**

### No change in the formal oxidation state of the metal

A vacant coordination site is generated during a migratory insertion (*which gets occupied by the incoming ligand*)

The groups undergoing migratory insertion must be *cis* to one another

These reactions are enthalpy driven and although the reaction is entropy prohibited the large enthalpy term dominates

# **Types of Migratory Insertion**
